

The benefit of this project (i.e., Secure Adaptable Application Logger) approach over existing logging tools, utilities or systems

Project goal: Protect application critical/sensitive log information from malicious and unauthorized users during software development and runtime deployment.

Log message risk: Software programs often generate unprotected log messages that contain critical and sensitive information about the execution flow of the software program and the data it uses during execution. Current approaches to protect log messages have been limited to protecting log messages after the software program has generated the log messages and saved to external storage.

Solution: To reduce this exposure, a holistic approach is needed to protect log data during the development of the software programs, during the generation of software program executables, and during runtime execution of executables.

Result: Prevent unauthorized users access to log messages in software programs (during development), executable program (from being reverse engineered), and runtime execution (from monitoring and extracting runtime data).

The free API library is the first step toward accomplishing the above objectives.
